## Summary

The presence of underwater military munitions (UWMM) in coastal and marine environments poses significant environmental and safety risks. Accurate detection and classification of UWMM are critical for remediation efforts, requiring robust methods to process multi-modal data, such as optical imagery and 3D reconstructions. UWMM detection leverages computer vision, machine learning, and 3D modeling to identify munitions against complex seabed backgrounds. Existing approaches, such as those only using image features (2D), often suffer from high false positive rates, necessitating the integration of geometric data (3D) to improve accuracy.

UWMM-Baseline is an open-source Python package designed for the supervised classification of UWMMs using multi-modal data, including optical imagery and depth-maps derived from 3D reconstructions of the scene. Building on the methodology of Gleason et al. (2015), the package implements a modular pipeline for dataset creation, feature extraction, classification, and evaluation. Key features include:

- **Dataset Creation:** Automated tile extraction and labeling from underwater imagery and depth-maps.
- **Feature Extraction:** Extraction of 2D-derived (color, texture) and 3D-derived (curvature, rugosity) features, which can be combined into a hybrid 2.5D feature set.
- **Classification:** Support for binary (UWMM vs. background) and multi-class (UWMM type) classification using Support Vector Machines (SVM).
- **Inference and Evaluation:** A complete inference pipeline to generate prediction masks on new data and quantitative evaluation using mean Intersection over Union (mIoU).
- **Modularity:** A flexible, configuration-driven framework allowing integration of new features, models, and data modalities.

UWMM-Baseline is designed for researchers, oceanographers, and environmental engineers working on UWMM detection, as well as educators teaching computer vision or marine science. It integrates with popular scientific Python libraries and supports workflows for both research and practical applications, such as seabed surveys and environmental monitoring.

## Statement of Need

UWMM detection is a pressing challenge in marine environments, where legacy munitions from military activities contaminate coastlines and pose risks to ecosystems and human safety. Traditional detection methods, such as acoustic or optical imagery, are often limited by resolution or seabed complexity. Optical imagery, combined with depth-maps, offers high-resolution data for precise UWMM identification, as demonstrated in Gleason et al. (2015).

40 However, existing software tools for UWMM detection are either proprietary, domain-specific,  
41 or lack the flexibility to handle multi-modal data in a unified framework.

42 UWMM-Baseline addresses this gap by providing a free, open-source, and modular Python  
43 package that implements established UWMM classification techniques using modern libraries.  
44 Unlike general-purpose computer vision libraries, UWMM-Baseline is tailored for underwater  
45 environments, incorporating domain-specific preprocessing and feature extraction (e.g., rugosity,  
46 curvature from depth-maps).

47 The package's modularity enables researchers to experiment with new features, classifiers, or  
48 data sources (e.g., sonar, stereo vision), while its accessibility supports educational use in  
49 courses on machine learning, oceanography, or environmental science. By providing a full  
50 pipeline from data ingestion to evaluation, UWMM-Baseline lowers barriers to entry for UWMM  
51 detection research, fostering innovation in environmental monitoring and remediation.

## 52 Background

**Figure 1:** Inference output of the UWMM baseline model. The leftmost image represents the output of the model trained exclusively on 2D-derived features, the central image shows the output of the model trained exclusively on 3D-derived features, and the rightmost image illustrates the output of the model trained on 2.5D extracted features.

53 The detection of UWMM in underwater environments involves processing optical imagery  
54 to identify munitions against varied seabed backgrounds (e.g., coral reefs, seagrass). The  
55 core challenge lies in distinguishing human-made objects from similarly shaped or textured  
56 natural features. It was demonstrated that while 2D-derived features (color, texture) achieve  
57 moderate accuracy (>80% for binary classification), they suffer from high false positives  
58 due to background complexity (Gleason et al., 2015). Incorporating 3D-derived features  
59 (e.g. curvature, rugosity) from depth-maps significantly improves accuracy (89-95%) and  
60 reduces false positives, as these features capture the distinct geometric properties of munitions.  
61 This combined, hybrid approach is referred to as the 2.5D approach.

62 The methodology is broken down into a multi-stage pipeline. First, large survey images are  
63 processed into smaller, manageable tiles. This approach allows the model to learn local,  
64 high-resolution features and creates a large, diverse dataset suitable for training supervised  
65 machine learning models. The general workflow is as follows:

- 66 1. **Dataset Creation:** Optical images, depth maps, and ground-truth masks are used to  
67 generate a labeled dataset of image tiles.
- 68 2. **Feature Extraction:** A comprehensive set of 2D-derived and 3D-derived features is  
69 extracted from each tile.
- 70 3. **Model Training:** A classifier, such as an SVM, is trained on the extracted features.
- 71 4. **Inference:** The trained model is used to predict the locations of UWMM in new, unseen  
72 images.

5. **Evaluation:** The model's predictions are compared against ground-truth data to assess performance quantitatively.

This project implements this entire workflow in a configurable and automated pipeline, building on the foundational work of Gleason et al. (2015). to provide an accessible software tool.

Methodology

**Figure 2:** The implemented classification framework is depicted in the above flowchart. The left section outlines the primary stages of the pipeline, while the right section details the specific components and features utilized in each stage.

The UWMM-Baseline pipeline processes underwater images, depth-maps, and masks to generate a labeled dataset of uniformly sized tiles for training and testing. It identifies potential UWMM and background locations using masks, extracting corresponding square tiles from image and depth data. To address class imbalance, a fixed number of background tiles are sampled per image, and only a subset of available UWMM pixels are used as tile centers. Data augmentation is applied by rotating UWMM tiles at multiple angles.

From the processed tiles, 2D-derived and 3D-derived features are extracted, extending the feature set proposed in Gleason et al. (2015):

- **2D-derived Features (from optical images):**
  - **Color Histograms:** HSV color distributions to capture seabed and UWMM appearance.
  - **Local Binary Patterns (LBP):** Texture descriptors robust to illumination changes (Ojala et al., 1994).
  - **Gray Level Co-occurrence Matrix (GLCM):** Texture metrics (e.g., contrast, dissimilarity) for seabed characterization (Haralick et al., 1973).
  - **Gabor Filters:** Edge and texture detection across multiple scales and orientations (Granlund, 1978).

- **3D-derived Features (from depth maps):**
  - **Principal Plane Features:** Statistics of depth values, polynomial coefficients from a fitted surface, and rugosity (ratio of surface area to planar area).
  - **Curvatures and Normals:** Mean and Gaussian curvatures, shape index, curvedness, and surface normal vector statistics.
  - **Symmetry Features:** Gabor filters applied to depth maps to capture structural symmetry.

The classifier is implemented using a SVM (Cortes & Vapnik, 1995) with a radial basis function (RBF) kernel, approximated via the Nystroem method (Williams & Seeger, 2000). The model supports training on 2D-derived, 3D-derived, or combined 2.5D feature sets. Prior to inference, superpixel segmentation (Achanta et al., 2012) identifies homogeneous regions in the input image. These regions are subdivided into overlapping tiles, each processed by the trained model to predict class labels. A neighborhood poll determines UWMM presence by evaluating whether the number of positive tile predictions within a region exceeds a predefined threshold. The final output is a segmentation mask indicating detected UWMM locations (see Figure 1).

This implementation leverages standard Python libraries, including NumPy (Harris et al., 2020), OpenCV (Bradski, 2000), scikit-learn (Pedregosa et al., 2011), scikit-image (Walt et al., 2014), and SciPy (Virtanen et al., 2020) for feature extraction, model training, and data processing.

### Model Training and 3D-derived Feature Extraction

The classification pipeline in UWMM-Baseline relies on feature extraction and SVM-based classification. For a tile  $\mathbf{x} \in \mathbb{R}^{m \times n}$  (image) and corresponding depth-map  $\mathbf{d} \in \mathbb{R}^{m \times n}$ , the feature vector  $\mathbf{f}_{2.5D}$  combines 2D-derived and 3D-derived features:

$$\mathbf{f}_{2.5D} = [\mathbf{f}_{2D}, \mathbf{f}_{3D}]$$

The 3D-derived features,  $\mathbf{f}_{3D}$ , are extracted from the depth-map of each tile. This process involves several calculations to describe the geometry of the surface.

A 2D-derived polynomial surface of the third degree is fitted to the depth-map of a tile to model its shape (Shihavuddin et al., 2014). The equation for this surface is:

$$f(x, y) = p_1 + p_2x + p_3y + p_4x^2 + p_5xy + p_6y^2 + p_7x^2y + p_8xy^2 + p_9y^3$$

The nine coefficients of this polynomial ( $p_1, \dots, p_9$ ) are extracted through least-squares fitting and used as features (Shihavuddin et al., 2014).

Additional statistical features are calculated from the depth values ( $z_i$ ) within a tile, including the standard deviation, skewness, and kurtosis (Shihavuddin et al., 2014). With  $z_m$  as the mean depth,  $S$  as the standard deviation, and  $N$  as the number of data points, the skewness and kurtosis are calculated as:

$$\text{Skewness} = \frac{\sum (z_i - z_m)^3}{(N - 1)S^3}$$

$$\text{Kurtosis} = \frac{\sum_{i=1}^N (z_i - z_m)^4}{(N - 1)S^4}$$

With regards to surface curvature, the Gaussian ( $G$ ) and mean ( $M$ ) surface curvatures are first calculated from the partial derivatives of the depth map where the two principal curvatures,  $k_1$  and  $k_2$ , can then be derived (Shihavuddin et al., 2014):

$$k_1 = M + \sqrt{M^2 - G}$$

$$k_2 = M - \sqrt{M^2 - G}$$

130 These principal curvatures are then used to calculate a shape index ( $S$ ) and a curvedness index  
131 ( $C$ ):

$$S = \frac{2}{\pi} \arctan \left( \frac{k_2 + k_1}{k_2 - k_1} \right), \quad C = \sqrt{\frac{k_1^2 + k_2^2}{2}}$$

132 Finally, rugosity ( $r$ ) is computed to characterize the roughness of the seafloor habitat (Shi-  
133 havuddin et al., 2014). It is calculated by dividing the contoured surface area of the tile ( $A_s$ )  
134 by the area of its orthogonal projection onto the principal plane ( $A_p$ ):

$$r = \frac{A_s}{A_p}$$

135 Once the full feature vector is assembled, the SVM classifier solves the following optimization  
136 problem:

$$\min_{\mathbf{w}, b, \xi} \frac{1}{2} \|\mathbf{w}\|^2 + C \sum_{i=1}^N \xi_i$$

137 subject to:

$$y_i(\mathbf{w}^T \phi(\mathbf{f}_i) + b) \geq 1 - \xi_i, \quad \xi_i \geq 0, \quad i = 1, \dots, N$$

138 where  $\mathbf{w}$  is the weight vector,  $b$  is the bias,  $\xi_i$  are slack variables,  $C$  is the regularization  
139 parameter,  $\phi$  is the kernel mapping (RBF), and  $y_i$  are the class labels (Cortes & Vapnik, 1995).
